

CS2105

An *Awesome* Introduction to Computer Networks

Lecture 8: The Link Layer, Part I

Department of Computer Science
School of Computing

Lectures 8&9: The Link Layer

After the next 2 classes, you are expected to understand:

- ❖ the role of link layer and the services it could provide.
- ❖ how parity and CRC scheme work.
- ❖ different methods for accessing shared medium.
- ❖ how ARP allows a host to discover the MAC addresses of other nodes in the same subnet.
- ❖ the role of switches in interconnecting subnets in a LAN.

Lecture 8: Roadmap

6.1 Introduction to the Link Layer

6.2 Error Detection and Correction

6.3 Multiple Access Links and Protocols

6.4 Switched Local Area Networks

Kurose Textbook, Chapter 6
(Some slides are taken from the book)

Link Layer: Introduction (1/2)

- ❖ **Network layer** provides communication service between any two hosts.
- ❖ An IP datagram may travel through multiple routers and links before it reaches destination.

Link Layer: Introduction (2/2)

- ❖ **Link layer** sends datagram between adjacent nodes (hosts or routers) over a single link.
 - IP **datagrams** are encapsulated in link-layer **frames** for transmission.
 - Different link-layer protocols may be used on different links.
 - each protocol may provide a different set of services.

Routing: Big Picture

Hub or Switch =

DHCP protocol provides:

- IP address, e.g., 192.168.0.x/24
- Subnet mask, e.g., 255.255.255.0
- IP of DNS server
- IP of Default Gateway (e.g.: 192.168.0.1)

NAT router
(Default
Gateway)

Within subnet
• **ARP** protocol

Which link/path to choose?

Intra-AS routing

- **RIP, OSPF** protocols
- Distributed algo.
- Build routing table

Possible Link Layer Services (1/2)

❖ Framing

- Encapsulate datagram into frame, adding header and trailer.

❖ Link access control

- When multiple nodes *share* a single link, need to coordinate which nodes can send frames at a certain point of time.

humans at a
cocktail party
(shared air)

Possible Link Layer Services (2/2)

❖ Reliable delivery

- Seldom used on low bit-error link (e.g., fibre) but often used on error-prone links (e.g., wireless link).

❖ Error detection

- Errors are usually caused by signal attenuation or noise.
- Receiver detects presence of errors.
 - may signal sender for retransmission or simply drops frame

❖ Error correction

- Receiver identifies and corrects bit error(s) without resorting to retransmission.

Link Layer Implementation

- ❖ Link layer is implemented in “adapter” (aka NIC) or on a chip.
 - E.g., Ethernet card/chipset, 802.11 card
- ❖ Adapters are semi-autonomous, implementing both link & physical layers.

Lectures 8&9: Roadmap

6.1 Introduction to the Link Layer

6.2 Error Detection and Correction

- 6.2.1 Parity Checks
- 6.2.3 Cyclic Redundancy Check (CRC)

6.3 Multiple Access Links and Protocols

6.4 Switched Local Area Networks

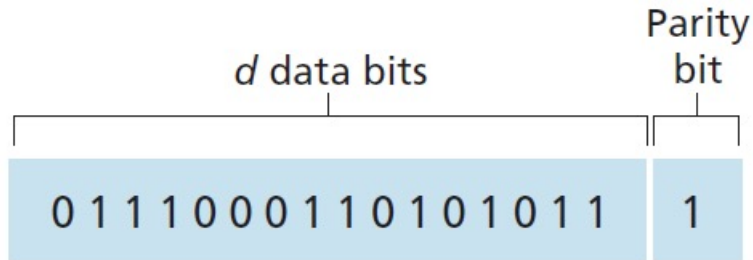

Error Detection and Correction

- ❖ Popular error detection schemes:
 - Checksum (used in TCP/UDP/IP)
 - Parity Checking
 - CRC (commonly used in link layer)
- ❖ Error detection schemes are not 100% reliable!
 - may miss some errors, but rarely.
 - larger error detection and correction (EDC) field yields better detection (and even correction).

Parity Checking

Single bit parity

- ❖ can detect single bit errors in data.

Two-dimensional bit parity

- ❖ can detect and correct single bit errors in data.
- ❖ can detect any two-bit error in data.

No errors

1	0	1	0	1	1
1	1	1	1	0	0
0	1	1	1	0	1
0	0	1	0	1	0

Cyclic Redundancy Check (CRC)

❖ Powerful error-detection coding that is widely used in practice (e.g., Ethernet, Wi-Fi)

- D : data bits, viewed as a binary number.
- G : generator of $r + 1$ bits, agreed by sender and receiver beforehand.
- R : will generate CRC of r bits.

Example: $r = 3$

 G
 D
 R

Cyclic Redundancy Check (CRC)

- ❖ CRC calculation is done in bit-wise XOR operation without carry or borrow.
- ❖ Sender sends (D, R)
101110011
- ❖ Receiver knows G , divides (D, R) by G .
 - If non-zero remainder: error is detected!

Example: $r = 3$

Lectures 8&9: Roadmap

6.1 Introduction to the Link Layer

6.2 Error Detection and Correction

6.3 Multiple Access Links and Protocols

- 6.3.1 Channel Partitioning Protocols
- 6.3.2 Random Access Protocols
- 6.3.3 Taking-Turns Protocols

6.4 Switched Local Area Networks

Two Types of Network Links

❖ **Type 1: point-to-point link**

- A sender and a receiver connected by a dedicated link
- Example protocols: Point-to-Point Protocol (PPP), Serial Line Internet Protocol (SLIP)
 - No need for multiple access control

A host connects to router through a dedicated link

RJ45

A point-to-point link between Ethernet switch and a host

Two Types of Network Links

- ❖ **Type 2: broadcast link** (shared medium)
 - Multiple nodes connected to a shared broadcast channel.
 - When a node transmits a frame, the channel broadcasts the frame and each other node receives a copy.

802.11 Wi-Fi

Satellite

Ethernet with bus topology

Multiple Access Protocols

- ❖ In a broadcast channel, if two or more nodes transmit simultaneously
 - Every node receives multiple frames at the same time
→ frames *collide* at nodes and none would be correctly read.
- ❖ Multiple Access Protocol
 - distributed algorithm that determines how nodes share channel, i.e. when a node can transmit.
 - However, coordination about channel sharing must use channel itself!
 - no out-of-band channel signaling

Multiple Access Protocols

❖ Multiple access protocols can be categorized into three broad classes:

- **Channel partitioning**

- divide channel into fixed, smaller “pieces” (e.g., time slots, frequency).
- allocate piece to node for exclusive use.

- **“Taking turns”**

- nodes take turns to transmit.

- **Random Access**

- channel is not divided, collisions are possible.
- “recover” from collisions.

Channel Partitioning Protocols

- ❖ **TDMA** (time division multiple access)
 - Access to channel in “rounds”.
 - Each node gets fixed length slot (length = frame transmission time) in each round.
 - Unused slots go idle.
 - Example: 6 nodes sharing a link, 1, 3, 4 have frames, slots 2, 5, 6 are idle.

Channel Partitioning Protocols

- ❖ **FDMA** (frequency division multiple access)
 - Channel spectrum is divided into frequency bands.
 - Each node is assigned a fixed frequency band.
 - Unused transmission time in frequency bands go idle.
 - Example: 6 nodes, 1, 3, 4 have frames, frequency bands 2, 5, 6 are idle.

Multiple Access Protocols

- ❖ Multiple access protocols can be categorized into three broad classes:
 - Channel partitioning
 - divide channel into fixed, smaller “pieces” (e.g., time slots, frequency).
 - allocate piece to node for exclusive use.
 - **“Taking turns”**
 - nodes take turns to transmit.
 - Random Access
 - channel is not divided, collisions are possible.
 - “recover” from collisions.

“Taking Turns” Protocols

Polling:

- ❖ master node “invites” slave nodes to transmit in turn.
- ❖ concerns:
 - polling overhead
 - single point of failure (master node)

“Taking Turns” Protocols

Token passing:

- ❖ control token is passed from one node to next sequentially.
- ❖ concerns:
 - token overhead
 - single point of failure (token)

Multiple Access Protocols

- ❖ Multiple access protocols can be categorized into three broad classes:
 - Channel partitioning
 - divide channel into smaller “pieces” (e.g., time slots, frequency).
 - allocate piece to node for exclusive use.
 - “Taking turns”
 - nodes take turns to transmit.
 - **Random Access**
 - channel is not divided, collisions are possible.
 - “recover” from collisions.

Random Access Protocols

- ❖ When node has packet to send
 - no *a priori* coordination among nodes
 - two or more transmitting nodes → “collision”
- ❖ Random access protocols specify:
 - how to detect collisions
 - how to recover from collisions (e.g., via delayed retransmissions)
- ❖ We will skip the mathematical formulas on the efficiency of random access protocols.

Slotted ALOHA

Assumptions:

- ❖ All frames are of equal size.
- ❖ Time is divided into slots of equal length (length = time to transmit 1 frame).
- ❖ Nodes start to transmit only at the beginning of a slot.

Operations:

- ❖ Listens to the channel while transmitting (**collision detection**).
- ❖ *if collision happens*: node retransmits a frame in each subsequent slot with probability p until success.

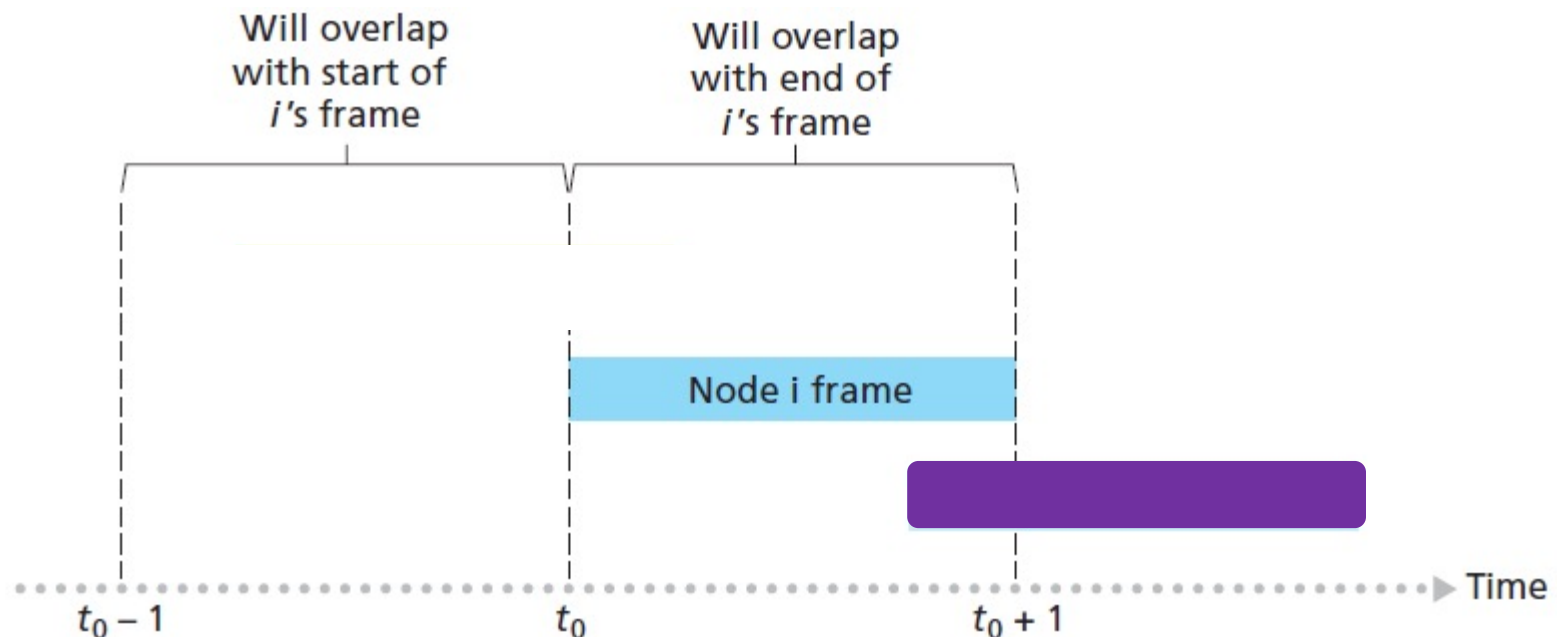

A Little Side Note

- ❖ **Q: Why is it called ALOHA?**
- ❖ **A:** The **ALOHAnet**, also known as the ALOHA System, or simply ALOHA, was a pioneering computer networking system developed – maybe you can guess it – at the University of Hawaii.
- ❖ Norman Abramson was the leader of the team.
- ❖ The idea was to use a radio network to connect Oahu and the other Hawaiian islands together. ALOHA made use of one, shared, inbound channel, and thus requiring a novel *multiple access protocol*.

Pure (unslotted) ALOHA

- ❖ Even simpler: no slot, no synchronization
 - When there is a fresh frame: transmit immediately
 - Chance of collision increases:
 - frame sent at t_0 collides with other frames sent in $(t_0 - 1, t_0 + 1)$

Carrier Sense Multiple Access

- ❖ **CSMA** (carrier sense multiple access)
 - Sense the channel before transmission:
 - if channel is sensed idle, transmit frame
 - if channel sensed busy, defer transmission
- ❖ Human analogy: don't interrupt others!
- ❖ **Q:** Will collision ever happen in CSMA?
 - collisions may still exist, e.g., when two nodes sense the channel idle at the same time and both start transmission.

CSMA Collisions

- ❖ Collisions can still occur:
 - **propagation delay** means two nodes may not hear each other's transmission immediately.

CSMA/CD (Collision Detection)

❖ CSMA/CD

- Carrier sensing & deferral as in CSMA
- When collision is detected, transmission is aborted (reducing channel wastage).
- Retransmit after a random amount of time.
 - An example algorithm will be given in the next lecture
- CSMA/CD is the underlying method of the early Ethernet, invented by Bob Metcalfe.

Minimum Frame Size

- ❖ What if the frame size is too small?
 - Collision happens but may not be detected by sending nodes.
 - No retransmission!
- ❖ For example, Ethernet requires a minimum frame size of 64 bytes.

A Little Side Note

- ❖ **Q:** Why was early Ethernet using CSMA/CD?
Nowadays Ethernet is mostly point-to-point, e.g., directly from a computer to a switch, so no need for multiple access.
- ❖ **A:** What we use today is called switched Ethernet. Switches are cheap and we connect every computer in a star-topology to a switch.
- ❖ In the early days, Ethernet was using a shared coaxial cable. Computers were connected to this one, long cable with **vampire taps** 😊.

CSMA/CA (Collision Avoidance)

- ❖ Collision detection is easy in wired LANs, but difficult in wireless LANs. For example,

Hidden node problem
(two laptops cannot
detect each other)

- ❖ 802.11 (Wi-Fi) uses CSMA/CA protocol instead.
 - Receiver needs to return ACK if a frame is received OK.

Lecture 8: Summary

❖ Channel partitioning

- Divide channel by time, used in GSM
- Divide channel by frequency, commonly used in radio, satellite systems

❖ Taking turns

- polling from central site, used in Bluetooth
- token passing, used in FDDI and token ring

❖ Random access

- CSMA/CD used in Ethernet
- CSMA/CA used in 802.11 Wi-Fi
